6

## The default hyperparameters :

- ❖ **Max\_epochs** : 60
- ❖ **Optimizer** : Adam with MultiStepLR
- ❖ **Batch size** : 16
- ❖ **Model** : LowRankSCLayer
- ❖ **Data** : ICVL dataset was used in the train and test :
  - Consists of **204** images of size **1392×1300** with **31 bands** (100 images for training, 50 for testing)
- ❖ **Constant Noise** : Gaussian noise added to all bands of an image with std=50

## Training :

- The **training** requires a significant amount of **resources** :
  - A **lot of memory** for processing a huge dataset of **27 GB**
  - A **GPU** with **CUDA** support for efficient computation

⇒ We used pre-trained models from the official repo on github

## Pre-processing :

- **Normalisation with GlobalMinMax** :
$$(x - \min(x)) / (\epsilon + \max(x) - \min(x))$$
- **Data augmentation** in train :
  - Random Horizontal Flip
  - Random Vertical Flip
  - Random Rotation with 90 degrees

# EXPERIMENTS

**IMT Atlantique**

École Mines-Télécom

Several metrics to evaluate the denoising quality :

- Peak Signal-to-Noise Ratio (PSNR)
- Structural Similarity (SSIM)
- Feature Similarity (FSIM)
- Relative dimensionless global error synthesis (ERGAS)

Note: We take the average of these metrics over the dataset.

Clean image

Noisy image

Denoised image

*Example of image denoising using T3SC model. The type of noised used here is constant noise.*

# CONCLUSION

**IMT Atlantique**

École Mines-Télécom

## About the code :

- Problems encountered to run the code because some libraries use an obsolete version
- The code is not easily flexible to new images. Difficult to apply the model to extra hyperspectral images with different characteristics (bands etc.)
- Multiple pre-trained models available for different noise types
- Good variety of the computed metrics

## About the T3SC model :

- Sensor-specific model
- Based on a strong mathematical background about sparse coding
